

### **OVERVIEW**

# **ASDO ANCHORS FOR MARINE STRUCTURES**

Anker Schroeder manufacture anchors for retaining structures such as quay walls, abutments, berths and crane runways. Our anchors range in diameter from M64 to M170 and can be supplied in grades 355, 460, 500 & 700. Anker Schroeder anchors are manufactured from round steel bar with forged or threaded ends that allow a variety of connections to be made to sheet piles, tubes, H-piles, combi-walls and diaphragm walls.

### STEEL GRADES

Anker Schroeder offer 4 standard steel grades for tie bars:

ASD0355
 M64 - M160
 M64 - M165

**⊙** ASD0500

**⊙** ASD0700

Diameter	N/mm²	N/mm²
M64 - M160	355	510
M64 - M165	460	610
M64 - M165	500	660
M64 - M170	700	900

The choice of steel grade depends on a number of factors, whilst the higher strength steel will always produce the lightest weight anchor this may not be suitable for stiffness requirements, onsite welding or lead-times. Other grades of steel are available please contact Anker Schroeder to discuss further.

Depending on diameter and length required Anker Schroeder tie bars are manufactured using selected fine grained steel, high strength low alloy steel or quench and tempered steel. The choice of steel is dependent upon your specific project requirements but the above minimum properties will be met. All tie bars and components are manufactured to a quality system audited and accredited to ISO 9001 and meet the requirements of EN1090 and are CE marked.

### **ASDO**

# **DESIGN CONSIDERATIONS**

# **ASDO ANCHORS FOR MARINE STRUCTURES**

### When designing anchors for retaining walls the following should be considered:

**Design Resistance** – the anchorage should be designed to provide sufficient design resistance to satisfy the design load required (note the design resistance is calculated differently between design codes).

Serviceability – the elongation of the anchors under the serviceability load

Puerto Caucedo, Dominique

may be the limiting factor rather than design resistance particularly where large crane loads have to be accommodated. Stiffness of an anchor is a function of the shaft diameter and subsequently a higher grade tie bar (e.g. ASD0700) may not be the most suitable. Movement under imposed loads may be reduced in many cases by pre-loading the anchors at the time of

MCT Berth 6, Manilla

installation to develop the passive resistance of the ground.

Pre-loading of the anchor is most easily achieved at a threaded end of the anchor by means of a hydraulic jack, consideration to the practicality of this should be made at design stage.

Stressing operation

Settlement - the effect of sag of the anchor and forced deflection due to settlement of fill may induce significant bending stresses at a fixed anchorage and increase the tensile stress in the tie rod locally. Shear stresses may also be induced into the thread if a tie rod is displaced when the fill settles causing compound stresses which must be allowed for in the detailed design. This can often be overcome by provision of articulated joints at connections to the

Whether a connection is articulated or fixed will affect the design resistance of the tie bar. If connections are fixed then a greater thread size must be used to accommodate any bending introduced to the anchor.

Settlement ducts can also be installed to reduce bending at the connection however these can be difficult and expensive to install and, if not aligned correctly, will not prevent settlement bending being introduced. If settlement ducts are used articulation at the wall connection is recommended to prevent bending due to the self weight of the bar as the duct moves. Further corrosion protection systems (such as wrapping) are essential particularly where there is a possibility of the duct acting as a conduit for seawater. Please contact our technical department for more information.

### Corrosion protection system

Anchor ties are typically used in aggressive environments and consequently corrosion protection factors influencing effective life must be considered. Consideration of the corrosion protection of the anchors at design stage and in particular the connection to the front wall is important as the anchor is typically subjected to the most aggressive environment at this point. Options include sacrificial steel, protective tape or coating systems. In most cases sacrificial steel provides the more economic and robust form of corrosion protection – see page 24 for more detail.

Bending stress induced by settlement or misalignment

Articulation removes bending stress at connection  $\alpha < 7^{\circ}$

# **ASDO**

# **DESIGN CONSIDERATIONS**

# TENSILE RESISTANCE OF TIE BARS

In accordance with EN1993-5 the tensile resistance F<sub>t Rd</sub> of an anchor is calculated as the lesser of the tensile resistance of the thread,  $F_{tt,Rd}$  or the tensile resistance of the shaft,  $F_{tq,Rd}$  at any time during the life of the structure.

Bending stress in thread induced by settlement or misalignment

It is important to note that the thread capacity of an anchor is reduced by the factor k<sub>t</sub>. According to EN1993-5 this is to allow for additional stresses that may be introduced due to settlement of fill or installation in less than ideal conditions.

 $F_{t,Rd}$  = lesser of:

 $F_{tg,Rd} = A_g x f_y / \gamma_{M0}$  $F_{tt,Rd} = k_t x f_{ua} x A_s / \gamma_{M2}$ 

A<sub>s</sub> = tensile stress area of thread

A<sub>a</sub> = gross cross sectional area of anchor

f<sub>v</sub> = yield strength of anchor material

 $f_{ua}$  = tensile strength of anchor material

k, = a reduction factor allowing for combined bending and tension in the thread (typically 0.6 where bending at the connection must be considered and 0.9 where structural detailing eliminates bending at the connection)

 $\gamma_{M0}$  &  $\gamma_{M2}$  = partial factors accord. EN1993 typically 1.0 & 1.25 respectively

In accordance with many EN1993-5 National Annexes a conservative k, value of 0.6 should be used unless structural detailing at the connection eliminates any possible bending when 0.9 can be used. However fully eliminating bending can be difficult, often settlement ducts are used but typical site conditions hinder proper installation of these as well as failing to provide restraint to the bending introduced by the self weight of the anchor as the duct moves with the fill.

Alignment of anchors, especially for diaphragm walls, is also difficult along with accurate prediction of settlement.

Therefore Anker Schroeder recommend that a k. factor of k. 0.6 is used in combination with articulated connections, this can also have benefits for corrosion resistance – see page 24.

It is for this reason Anker Schroeder have developed a full range of upset forged ends for tie bars. Upset forging allows threads to be increased in size with little additional weight being added to the anchor. By increasing the thread diameter bending stresses can be minimised and sacrificial steel can be easily added to the threaded portion, often the most vulnerable part of an anchor.

Only upset forged threads ensure that the shaft is the weakest part of a tiebar anchor. This has benefits as, in the unfortunate event of structural failure, the shaft will realise it's full elongation capacity giving greater warning of serviceability failure of the pile wall.

Upset forged thread advantage stress area of thread > stress area of shaft

upset forged thread  $A_s > A_g$ variable ratio A<sub>s</sub>/A<sub>q</sub>

cross sectional area of shaft

standard rolled thread  $A_s = A_a$ fixed ratio A<sub>s</sub>/A<sub>a</sub>

### Upset forging

Unlike traditional forging in which a parent metal is heated and forged into a smaller dimension upset forging is a process by which parent metal is increased in sectional area. In the case of anchors this allows the ends of a bar to be increased in section and threads cut or rolled onto the forged cylinder. The same process can also be used to form articulated ends such as eyes or spherical ends.

Chart showing the weight per metre advantage for upset forged anchors compared to standard threaded anchors.

### Design example

### Design criteria:

Design ultimate load for anchor,  $F_{Ed} = 2,200 \text{ kN}$ 

Tie bar length = 45m (calculated in accordance with EN1997)

Serviceability characteristic load,  $F_{tser} = 1,600 \text{ kN}$ 

Tie bar extension limit = 100 mm

Design life structure = 50 years

Thread notch factor - use recommended value  $k_t = 0.6$  (see EN1993-5 National UK Annex)

### Size selection

Minimum Anchor size required – Clause 7.2.3 EN1993-5

From table 2 grade ASD0500,  $k_t = 0.6$  select M100/76 anchor

Design tensile resistance  $F_{t,Rd}$  = 2,216 kN > 2,200 kN  $\cdot\cdot$  0K

Thread = M100 (stress area,  $A_s = 6,995 \text{ mm}^2$ ) Shaft = 75 mm diameter (stress area  $A_0 = 4,536 \text{ mm}^2$ )

 $= 500 \text{ N/mm}^2$ ,  $f_{ua} = 660 \text{ N/mm}^2$ 

Note: Clause 7.2.3(4) EN1993-5 states that the design provisions given do not cover the occurrence of bending in the thread. It is recommended by EN1993 & EAU that connections to the wall be articulated to provide sufficient rotation tolerance (further articulation at points of maximum bending along the bar should also be considered).

Further checks may be required for combined bending and axial load checks in both the thread and shaft due to settlement of the fill. The use of upset threads and a  $k_t$  factor of 0.6 will give greater capacity in the areas of likely bending giving a greater safety factor. For the above example the tie bar arrangement in the figure opposite can be made.

### Serviceability check

Elongation under axial characteristic loading

 $F_{tser} = 1,600 \text{ kN}$ 

Stress in shaft =  $\frac{1,600 \times 10^3}{4,536}$  = 353 N/mm<sup>2</sup>

Elongation =  $\frac{353 \times 45,000}{210 \times 10^3} = 76 \text{ mm} < 100 \text{ mm} \cdot \cdot \cdot \cdot 0 \text{ K}$ 

Where elastic modulus =  $210 \text{ kN/m}^2$ 

Hint – if the elongation is too great try a larger diameter of a lesser grade.

Serviceability limit state - Clause 7.2.4 EN1993-5

The required additional check for serviceability in this example is already implied in the resistance check  $F_{Rd} < F_{Ed}$  as a  $k_t$  factor of 0.6 has been used, however it is performed here for information.

$$\mathsf{F}_{\mathsf{t},\mathsf{ser}} \leq \qquad \frac{\mathsf{f}_{\mathsf{y}} \mathsf{A}_{\mathsf{s}}}{\gamma \, \mathsf{M}_{\mathsf{t},\mathsf{ser}}} \qquad \text{where } \mathsf{A}_{\mathsf{s}} \, \mathsf{is} \, \mathsf{the} \, \mathsf{lesser} \, \mathsf{of} \\ \mathsf{shaft} \, \mathsf{area} \, \mathsf{or} \, \mathsf{thread} \, \mathsf{area}$$

$$1,600 \text{ kN} \le \frac{500 \times 4,536}{1.1 \times 10^3} \le 2,062 \text{ kN} :: \text{OK}$$

Consider corrosion resistance – for robustness and simplicity in handling and installation use sacrificial steel. The tie bar is split into zones as per the diagram below. The corrosion rate assumed for each zone depends on local conditions, or the guidance given in EN1993-5 can be considered. The rates given below are for example only.

Each zone is considered in turn and the expected corrosion rate added to the minimum size, as per the table below. Note the corrosion rate assumed for zone one can be reduced considerably by placing the anchor connection head behind the sheet pile pan as shown on page 12 and detail Z page 20.

Zone	Description	Environment	Corrosion allowance		including allowance	Nearest s	andard size
				Thread	shaft	Thread	shaft
1	Anchor head	Splash zone, aggressive	3.75 mm (from table 4.2 EN1993-5)	107.5	83.5 mm	M110	85 mm
2	Immediately behind wall	Non-aggressive compacted fill, possibility of seawater entering through connection to front wall	2.0 mm (assumed)	-	80 mm	-	85 mm (same bar as zone 1)
3	Remainder of tie bar	Non-aggressive compacted fill	1.2 mm (from table 4.1 EN1993-5, compaction reduction ignored for conservatism)	102.4	78.4 mm	M105	80 mm

### Final specification

As a minimum the following information is required in order to specify the anchors correctly.

Anchors:

Grade ASD0500 - M110/85, M105/80 with articulated connections, turnbuckles and length as indicated on drawing Minimum design resistance,  $F_{1,Rd}$  = 2,200 kN (after corrosion losses)

 $k_t = 0.6$  (in accordance with EN1993-5)

 $f_v = 500 \, \text{N/mm}^2$ 

 $f_{112} = 660 \text{ N/mm}^2$ 

Corrosion protection = sacrificial steel to all bars and components as indicated

# **ASDO**

# **PRODUCT**

# TYPICAL CONNECTIONS

### Connections to sheet piles

Forces are transferred from the sheet pile to the anchor bar through waling sections that run the length of the wall. At the front wall these are normally placed behind the wall (i.e. earth side) and at the anchor wall the non-bearing side.

Steel Z-pile with spherical nut (articulated)

# culation can be provided that allows movement in the vertical direction or in all directions.

Anchor forces are generally high and articulated connections

are recommended to minimize bending at the connection. Arti-

Connections to high modulus piles

### Anchor connection to inside of

### Anchor connection to outside of pile pan

Anchor connec-

tion to outside of

pile pan

### Anchor forces are transferred directly to the anchor wall via the waling. Generally waling bolts are not required.

Anchor wall

connection

### Steel U-pile with spherical nut (articulated)

### Anchor connection to inside of pile pan

Anchor forces are transferred directly to the anchor wall via the waling. Generally waling bolts are not required.

Anchor wall

connection

### Connections to concrete walls

Alignment between the front wall and anchor wall connection points is critical. Simple articulated connections allow easy casting into the wall without difficult interruption to formwork and allow easy connection once the wall has cured. Articulated joints are strongly recommended to aid installation.

Combi & diaphragm wall connections (articulated)

Combi wall - cast-in forged eye A forged eye bar is cast into the tube transferring forces to the centre of the tube. The anchor bars are attached to the cast-in bar via link plates allowing articulation in the vertical direction.

Combi wall cast-in T-Plate A fabricated T-Plate is cast into the tube transferring forces to the centre of the tube. Forged eye anchor bars are attached to the T-connector via a pin allowing articulation in the vertical direction. See table 7 for more detail.

Combi & D-wall cast-in spherical box A machined 'spherical box is cast into the tube transferring forces to the centre of the tube. Forged spherical anchor bars are connected to the box allowing articulation in both the vertical & horizontal directions.

### HZ-M-pile connections (articulated)

### HZ-M wall tension plates

Machined and factory welded tension plates are placed either side of the HZ-M web and passed through burnt holes in the flange. Forces are transferred from the transition radius of the HZ-M to the forged eye anchor bar through a pin connection and articulation in the vertical plane is possible. See table 6 for more detail.

### Double HZ-M wall tension beam

A factory welded tension beam is placed bearing on HZ-M flanges close to the web and tension plates passed through burnt holes in the flange. Forces are transferred to the anchor bar through a pin connection and articulation in the vertical plane is possible.

Coupler
Couplers and turnbuckles are used to connect bars to make
longer lengths. A turnbuckle can be used for length adjustment.

Articulated turnbuckle
An adjustable turnbuckle allows length adjustment and articulation in one plane.

Link plates

Together with forged eyes link plates provide the most economic articulated joint and the simplest connection to achieve in site conditions.

Cardan joint

The cardan joint allows bars with forged eyes to articulate in both vertical and horizontal planes.

# **WALINGS**

# DESIGN CONSIDERATIONS

Anker Schroeder can supply complete waling systems to suit a variety of wall configurations. Waling usually comprises of two rolled steel channel sections placed back to back and spaced to allow the tie rods to pass between the channels. This spacing must allow for the diameter of the tie rod and the thickness of any protective material applied to the rod and take into account any additional space required if the tie rods are inclined and need to pass between the walings at an angle.

Note: The combination of anchor head connections to the outside and inside of the sheet pan is shown for example only and would not normally be used in practice.

.....

Detail X

Detail Z

Tie bar connection inside sheet pile pan for additional corrosion protection

Detail Y
Tie bar connection outside sheet pile

Anchor connections to a sheet pile wall can be made in two ways – outside the wall or inside as shown opposite. Generally walings placed inside the retaining wall are preferred both for aesthetic reasons and, in the case of a wall in tidal or fluctuating water level conditions, to prevent damage to the waling by floating craft or vice versa.

Placing the waling inside the wall also allows the anchor bar to be connected inside the wall within the pan of a sheet pile. This greatly increases the corrosion protection to the main tie bar connection, see detail Z.

When the waling is placed behind the front wall, it is necessary to use waling bolts and plates at every point of contact between the piles and the waling to ensure load is transferred fully to the waling.

Anker Schroeder supply a complete range of waling bolts to suit project applications. Bolt heads are forged on to the bar and if these are placed on the outside of the wall provide greater corrosion protection than exposed threads such as hexagon nut connections.

For design purposes the waling can be considered as continuous with allowance being made for end spans. Although the waling is then statically indeterminate, it is usual to adopt a simplified approach where the bending moment is assumed to be wL²/10, being the calculated load to be supplied by the

anchorage system acting as a uniformly distributed load and L is the span between anchors.

When checking the anchorage system for the loss of a single anchor, the load in the anchorage system is assessed on the basis of the requirements for a serviceability limit state analysis with no allowance being made for overdig at excavation level. The resulting bending moments and tie forces are considered to be ultimate values and are applied over a length of waling of 2L.

In this extreme condition, it can be demonstrated that, with the exception of the anchors at either end of the external spans, the bending moment in a continuous waling resulting from the loss of any tie rod will not exceed  $0.3~\text{wL}^2$  where w is the support load calculated for this condition expressed as a UDL and, for simplicity, L is the original span between anchors.

Typical waling sizes and grades along with theoretical bending capacities are given in table 12. It is intended that these values are used for estimation only and provide an initial assessment to which waling section may be suitable. For complete assessment of structural requirements a more rigorous analysis taking into account factors such as torsion, axial loading and high shear loads should be made.

plain for cutting and drilling on site, after

the actual length required has been de-

termined. Where inclined ties are used,

load must not be overlooked and provisi-

on must be made to support the waling,

the vertical component of the anchor

The above sizes are the most common used – other sections can be provided on request.

Waling splice detail

Port, Reykjavik

For longer lengths walings can be joined usually in the form of brackets or welded by splice sections. These should be loca- connections. Where sheet pile anchor ted at a distance of 0.28 of the anchor walls are used, similar walings to those at spacing from an anchor location as this the retaining wall are required. These are will be close to the position of minimum always placed behind the anchor piles and bending moment in the waling. The waconsequently no waling bolts are required. lings should be ordered 100 mm longer Where higher waling loads are found, e.g. than the theoretical dimensions to allow for combi-walls, Anker Schroeder can for any creep which may develop in the offer walings fabricated from higher inerwall as the piles are driven. Splice contia sections, e.g. H sections – please connections can be welded or bolted, if boltact our sales department for more inforted only one end of the waling length is drilled for splicing to match the splice hole pattern. The other end is supplied

Where walings form part of the permanent structure they can be supplied with protective coatings or often more economical a sacrificial steel allowance made. If coatings are supplied then further coatings are recommended on site after installation.

Waling bolts are made from the same grades of steel as ASD0355 & ASD0500. Bolts can be made with forged hexagon heads or threaded each end, lengths are made to order. Standard hexagon nuts are provided.

**DESIGN** 

# **CORROSION PROTECTION**

Marine structures inherently operate in aggressive environments and selection of robust protection systems for tie bars is key to the longevity of a structure. It is very important to consider the corrosion protection of the anchors at design stage and of particular importance is the connection to the front wall as the anchor is typically subjected to the most aggressive environment at this point and this is the most common area of failure for an anchorage.

Tables 4-1 & 4-2 of EN1993-5 give guidance to corrosion allowances for steel sheet piles, it is accepted practice to use these same rates for tie bars.

Corrosion protection for anchors can be provided in several ways.

### Sacrificial steel

Anker Schroeder consider sacrificial steel to be the most practical and robust corrosion protection. The anchor shaft and thread size are increased in diameter to allow for corrosion steel loss during the life of the structure. No additional coating is required.

The figure below shows how the threaded part of the anchor in the splash zone has been increased in diameter to allow for the anticipated corrosion loss. This system is robust as no special transport or site considerations are required.

By calculation use Grade ASD0500 Shaft diameter required 76 mm

Thread diameter required

Sacrificial corrosion allowance in fill

1.2 mm

Sacrificial corrosion allowance at head

3.75 mm

Anchor shaft size required = 83.5 mm and thread size M110.

Therefore use ASD0500 M110/85.

Note: The shaft and thread can be reduced as the corrosion rate decreases (see page 11).

Table 14 - Corrosion allowances for steel anchors

EN1993-5 Table 4-1 - Recommended value for the loss of steel thickness (mm) due to corrosion in soils with or without groundwater

Required design working life	5 years	25 years	50 years	75 years	100 years
Non-compacted and non-aggressive fills (clay, schist, sand, silt)	0.18	0.7	1.2	1.7	2.2

Note: For compacted fills EN1993-5 allows the corrosion rates above to be halved EN1993-5 Table 4-2 - Recommended value for the loss of steel thickness [mm] due to corrosion in fresh water or sea water.

EN1993-5 Table 4-2 - Recommended value for the loss of steel thickness (mm) due to corrosion in water

Required design working life	5 years	25 years	50 years	75 years	100 years
Common fresh water (river, ship canal) in the zone of high attack (water line)	0.15	0.55	0.9	1.15	1.4
Very polluted fresh water (sewage, industrial effluent) in the zone of high attack (water line)	0.3	1.3	2.3	3.3	4.3
Sea Water in temperate climate in the zone of high attack (low water and splash zones)	0.55	1.9	3.75	5.6	7.5
Sea Water in temperate climate in the zone of permanent immersion or in the intertidal zone	0.25	0.9	1.75	2.6	3.5

### Wrapping systems

The most commonly used wrapping system is to cover the anchors in a protective barrier such as petrolatum tape (e.g. Denso).

latum wrapped bar, but it should be remembered, that connections cannot be wrapped until installed on site and can increase installation time considerably.

The vulnerable anchor head can only be fully protected once installed and this is often difficult to achieve in site condi-

It is important to ensure that protection to connections and the anchor head are correctly performed during installation. any damaged or unprotected areas must be repaired before backfilling.

Factory wrapping of anchors

**Anchorage Fabrications** 

complex constructions.

Anker Schroeder can also supply anchorage distribution units for more

**Galvanised T-plates** 

With the exception of ASD0700 bar Anker Schroeder tie bars and components can be hot dip galvanised to EN ISO 1461 but consideration should Anker Schroder can offer factory petro- be given to threads which are unable to have more than a nominal coating of zinc. Please contact our technical department for further detail.

### Painting

Galvanising

Anchors can have any suitable paint system applied as required by the client. Consideration should be given to likely damage that will occur to the paint system during transport and installation as any break in the protective system could lead to pitting corrosion.

Please contact our technical department for further detail.

Storage of wrapped anchors

Galvanised anchors

**General Note** 

Any breaks in the protective system could lead to aggressive pitting corrosion and premature failure of the anchor. To discuss these issues further, please contact our technical department.

# **GENERAL INFORMATION**

# SITE INFORMATION

### Storage of anchors

Tie rods and accessories shall be stored and handled in such a way as to avoid excessive deformation, corrosion, exposure to heat (e.g. flame cutting), bending or damage of any kind being caused on the rods, threaded ends, turnbuckles or nuts.

tected from dust, dirt and damage. Clean assembled on site to design lengths. and check all threads thoroughly before use.

ried out on the tie rods and/or accessories (turnbuckles, couplers, nuts) without ded connections must be made with miwritten approval of ASDO. All tie bars and nimum engagement of at least 1 x diaaccessories should be protected from any exposure to heat processes on site such as welding or flame cutting.

### Assembly

Container or road shipping restrictions generally mean that anchors are delivered in sections of typically 12 m or less, however Anker Schroeder have direct rail links and convenient access to docks where longer lengths can be shipped - please contact our technical All threaded parts must be carefully pro- team for further detail. Sections are Assembly on a clear hard-standing with roller trestles is recommended. Great care should be taken in ensuring No welding or flame cutting shall be carthreads are clean and free of dirt and damage prior to assembling. All threameter of the thread.

### Installation

Anchors should be installed as close as possible to the line of force that they will experience during service. Account should be taken of the additional forces that will be introduced to the bar by settlement of the fill, particularly bending at the wall

Long anchors should be lifted by use of a stiff lifting beam with supports at approximately every 4-6 m.

### Site services & training

Anker Schroeder are able to offer training for assembly, installation and stressing either at your site or at our factory in Dortmund. Please contact our technical department for more information.

### Stock and availability

Anker Schroeder hold over 4,000 tonnes of raw material enabling many projects to be quickly supplied with initial needs. However most major projects will require the bulk of raw material to be rolled to the specific project diameter which can be adapted to the nearest millimetre to ensure the most economical solution. Please contact our sales department to discuss your project requirements.

# OTHER PRODUCTS

ASDO Stainless Architectural tie bars

Diameter M12 to M56

ASD0 Structural Architectural tie bars

Diameter M12 to M160

ASDO Micro Piles

Diameters up to M160 and working loads > 3,000 kN

ASDO Forged Shackles

Working load capacities up to 1500 tonnes

This publication provides information and technical details currently used by Anker Schroeder in the manufacture of its products.

Although we have taken great care in the preparation of the data within this publication, we cannot assume responsibility for the completeness and accuracy of all the details given. Each customer should satisfy themselves of the product suitability for their requirements. The publication of this data does not imply a contractual offer.

In line with Anker Schroeder's policy of continuous improvement the company reserves the right to change or amend details. Please contact our technical department for further information or to ensure these details are current.

### Sustainability

Steel is the most recycled material in construction. All anchorage material supplied by Anker Schroeder is sourced from reputable steel mills and, where possible, up to 90% of melt is recycled steel. Once a structure has reached the end of it's design life Anker Schroeder Bars are 100% recyclable as scrap material but the economics and environmental impact of extraction from the structure need to be considered.
